■ GENERAL DESCRIPTION

The HM6264 is a high performance, high speed and super low power CMOS Static Random Access Memory organized as 8,192 words by 8bits and operates from a single 4.5V to 5.5V supply voltage. Advanced CMOS technology and circuit techniques provide both high speed, super low power features and maximum access time of 70ns in 5.0V operation. Easy memory expansion is provided by using two chip enable inputs (/CE1, CE2) and active LOW output enable (/OE).

The HM6264 has an automatic power down feature, reducing the power consumption significantly when chip is deselected. The HM6264 is available in JEDEC standard 28-pin SOP(300 mil) and PDIP (600 mil) packages.

■ FEATURES

■ PIN DESCRIPTIONS

Name	Type	Function
A0 – A12	Input	Address inputs for selecting one of the 8,192 x 8 bit words in the RAM
/CE1, CE2	Input	/CE1 is active LOW and CE2 is active HIGH. Both chip enables must be active when data read from or write to the device. If either chip enable is not active, the device is deselected and in a standby power down mode. The DQ pins will be in high impedance state when the device is deselected.
/WE	Input	The Write enable input is active LOW. It controls read and write operations. With the chip selected, when /WE is HIGH and /OE is LOW, output data will be present on the DQ pins, when /WE is LOW, the data present on the DQ pins will be written into the selected memory location.
/OE	Input	The output enable input is active LOW. If the output enable is active while the chip is selected and the write enable is inactive, data will be present on the DQ pins and they will be enabled. The DQ pins will be in the high impedance state when /OE is inactive.
DQ0~DQ7	I/O	These 8 bi-directional ports are used to read data from or write data into the RAM.
Vcc	Power	Power Supply
Gnd	Power	Ground
NC		No connection

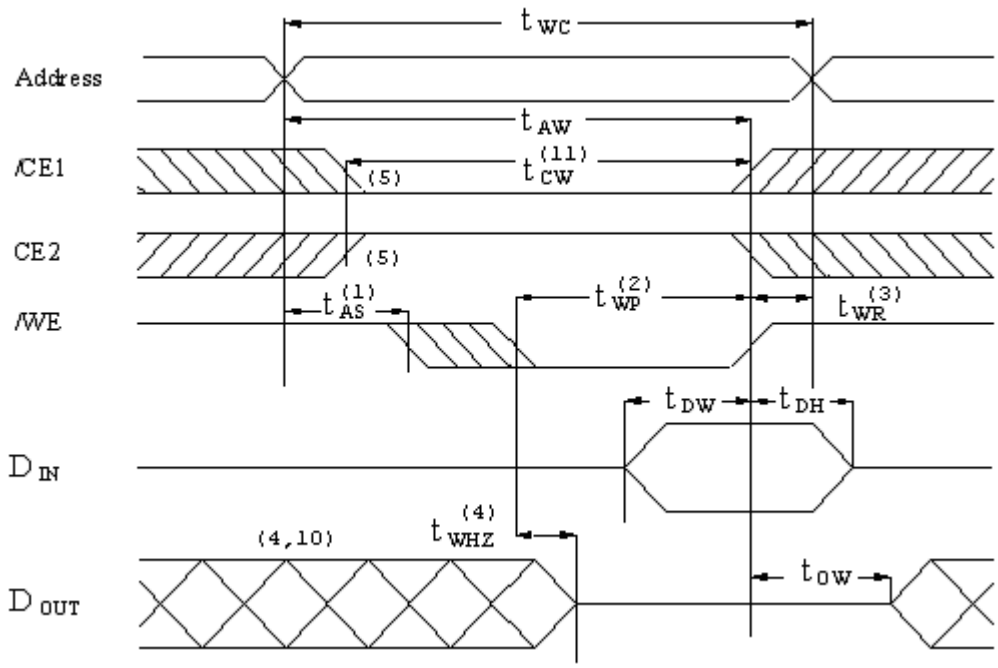
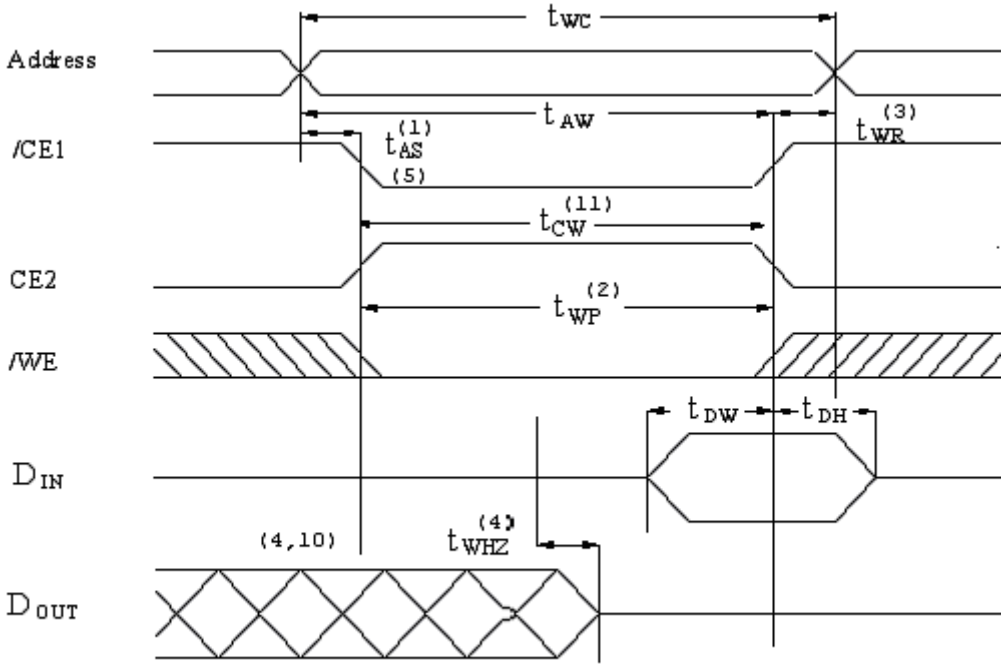
■ SWITCHING WAVEFORMS (WRITE CYCLE)

WRITE CYCLE1 (Write Enable Controlled)



WRITE CYCLE2 (Chip Enable Controlled)



NOTES:

1. T_{AS} is measured from the address valid to the beginning of write.
2. The internal write time of the memory is defined by the overlap of /CE1 and CE2 active and /WE low. All signals must be active to initiate a write and any one signal can terminate a write by going inactive. The data input setup and hold timing should be referenced to the second transition edge of the signal that terminates the write.
3. T_{WR} is measured from the earlier of /CE1 or /WE going high or CE2 going low at the end of write cycle.
4. During this period, DQ pins are in the output state so that the input signals of opposite phase to the outputs must not be applied.
5. If the /CE1 low transition or CE2 high transition occurs simultaneously with the /WE low transitions or after the /WE transition, output remain in a high impedance state.
6. /OE is continuously low (/OE = V_{IL}).
7. D_{OUT} is the same phase of write data of this write cycle.
8. D_{OUT} is the read data of next address.
9. If /CE1 is low and CE2 is high during this period, DQ pins are in the output state. Then the data input signals of opposite phase to the outputs must not be applied to them.
10. Transition is measured ±500mV from steady state with C_L = 5pF as shown in Figure 1B. The parameter is guaranteed but not 100% tested.
11. T_{CW} is measured from the later of /CE1 going low or CE2 going high to the end of write.
